

# Package ‘BGLR’

October 8, 2013

**Version** 1.0

**Date** 2012-09-12

**Title** Bayesian Generalized Linear Regression

**Author** Gustavo de los Campos, Paulino Perez Rodriguez,

**Maintainer** Paulino Perez Rodriguez <perpdgo@colpos.mx>

**Depends** R (>= 2.12.2)

**Description** Bayesian Generalized Linear Regression

**LazyLoad** true

**License** GPL-3

**Description**

The BGLR ('Bayesian Generalized Linear Regression') function fits various types of parametric and semi-parametric Bayesian regressions to continuous (censored or not), binary and ordinal outcomes.

**Usage**

```
BGLR(y, response_type = "gaussian", a=NULL, b=NULL, ETA = NULL, nIter = 1500,
      burnIn = 500, thin = 5, saveAt = "", S0 = NULL,
      df0 = 5, R2 = 0.5, weights = NULL,
      verbose = TRUE, rmExistingFiles = TRUE)
```

**Arguments**

- |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y             | (numeric, <i>n</i> ) the data-vector (NAs allowed).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| response_type | (string) admits values "gaussian" or "ordinal". The Gaussian outcome may be censored or not (see below). If response_type="gaussian", y should be coercible to numeric. If response_type="ordinal", y should be coercible to character, and the order of the outcomes is determined based on the alphanumeric order (0<1<2...<a<b...). For ordinal traits the probit link is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| a, b          | (numeric, <i>n</i> ) only required for censored outcomes, a and b are vectors specifying lower and upper bounds for censored observations, respectively. The default value, for non-censored and ordinal outcomes is NULL (see details).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| ETA           | <p>(list) This is a two-level list used to specify the regression function (or linear predictor). By default the linear predictor (the conditional expectation function in case of Gaussian outcomes) includes only an intercept. Regression on covariates and other types of random effects are specified in this two-level list. For instance:</p> <pre>ETA=list(list(X=W, model="FIXED"), list(X=Z, model="BL"), list(K=G, model="RKHS")),</pre> <p>specifies that the linear predictor should include: an intercept (included by default) plus a linear regression on W with regression coefficients treated as fixed effects (i.e., flat prior), plus regression on Z, with regression coefficients modeled as in the Bayesian Lasso of Park and Casella (2008) plus and a random effect with co-variance structure G.</p> <p>For linear regressions the following options are implemented: BRR (Gaussian prior), BayesA (scaled-t prior), BL (Double-Exponential prior), BayesB (two component mixture prior with a point of mass at zero and a scaled-t slab), BayesC (two component mixture prior with a point of mass at zero and a Gaussian slab). In linear regressions X can be the incidence matrix for effects or a formula (e.g. ~factor(sex) + age) in which case the incidence matrix is created internally using the model.matrix function of R. For Gaussian processes (RKHS) a co-variance matrix (K) must be provided. Further detail about the models in BGLR see the vignettes in the package or <a href="http://genomics.cimmyt.org/BGLR.pdf">http://genomics.cimmyt.org/BGLR.pdf</a>.</p> |

weights	(numeric, $n$ ) a vector of weights, may be NULL. If weights is not NULL, the residual variance of each data-point is set to be proportional to the square of the weight. Only used with Gaussian outcomes.
nIter, burnIn, thin	(integer) the number of iterations, burn-in and thinning.
saveAt	(string) this may include a path and a pre-fix that will be added to the name of the files that are saved as the program runs.
S0, df0	(numeric) The scale parameter for the scaled inverse-chi squared prior assigned to the residual variance, only used with Gaussian outcomes. In the parameterization of the scaled-inverse chi square in BGLR the expected values is $S0/(df0-2)$ . The default value for the df parameter is 5. If the scale is not specified a value is calculated so that the prior mode of the residual variance equals $\text{var}(y)*R2$ (see below). For further details see the vignettes in the package or <a href="http://genomics.cimmyt.org/BGLR.pdf">http://genomics.cimmyt.org/BGLR.pdf</a> .
R2	(numeric, $0 < R2 < 1$ ) The proportion of variance that one expects, a priori, to be explained by the regression. Only used if the hyper-parameters are not specified; if that is the case, internally, hyper-paramters are set so that the prior modes are consistent with the variance partition specified by R2 and the prior distribution is relatively flat at the mode. For further details see the vignettes in the package or <a href="http://genomics.cimmyt.org/BGLR.pdf">http://genomics.cimmyt.org/BGLR.pdf</a> .
verbose	(logical) if TRUE the iteration history is printed, default TRUE.
rmExistingFiles	(logical) if TRUE removes existing output files from previous runs, default TRUE.

## Details

BGLR implements a Gibbs sampler for a Bayesian regression model. The linear predictor (or regression function) includes an intercept (introduced by default) plus a number of user-specified regression components (X) and random effects (u), that is:

$$\eta = 1\mu + X_1\beta_1 + \dots + X_p\beta_p + u_1 + \dots + u_q$$

The components of the linear predictor are specified in the argument ETA (see above). The user can specify as many linear terms as desired, and for each component the user can choose the prior density to be assigned. The distribution of the response is modeled as a function of the linear predictor.

For Gaussian outcomes, the linear predictor is the conditional expectation, and censoring is allowed. For censored data points the actual response value ( $y_i$ ) is missing, and the entries of the vectors a and b (see above) give the lower an upper bound for  $y_i$ . The following table shows the configuration of the triplet (y, a, b) for un-censored, right-censored, left-censored and interval censored.

	a	y	b
Un-censored	NULL	$y_i$	NULL
Right censored	$a_i$	NA	$\infty$
Left censored	$-\infty$	NA	$b_i$
Interval censored	$a_i$	NA	$b_i$

Internally, censoring is dealt with as a missing data problem.

*Ordinal outcomes* are modelled using the probit link, implemented via data augmentation. In this

case the linear predictor becomes the mean of the underlying liability variable which is normal with mean equal to the linear predictor and variance equal to one. In case of only two classes (binary outcome) the threshold is set equal to zero, for more than two classes thresholds are estimated from the data. Further details about this approach can be found in Albert and Chib (1993).

### Value

A list with estimated posterior means, estimated posterior standard deviations, and the parameters used to fit the model. See the vignettes in the package (or <http://genomics.cimmyt.org/BGLR.pdf>) for further details.

BLR

*Bayesian Linear Regression*

## Description

The BLR ('Bayesian Linear Regression') function was designed to fit parametric regression models using different types of shrinkage methods. An earlier version of this program was presented in de los Campos *et al.* (2009).

## Usage

```
BLR(y, XF, XR, XL, GF, prior, nIter, burnIn, thin, thin2, saveAt,
    minAbsBeta, weights)
```

## Arguments

y	(numeric, $n$ ) the data-vector (NAs allowed).
XF	(numeric, $n \times p_F$ ) incidence matrix for $\beta_F$ , may be NULL.
XR	(numeric, $n \times p_R$ ) incidence matrix for $\beta_R$ , may be NULL.
XL	(numeric, $n \times p_L$ ) incidence matrix for $\beta_L$ , may be NULL.
GF	(list) providing an \$ID (integer, $n$ ) linking observations to groups (e.g., lines or sires) and a (co)variance structure (\$A, numeric, $p_U \times p_U$ ) between effects of the grouping factor (e.g., line or sire effects). Note: ID must be an integer taking values from 1 to $p_U$ ; ID[i]= $q$ indicates that the $i$ th observation in $\mathbf{y}$ belongs to cluster $q$ whose (co)variance function is in the $q$ th row (column) of $\mathbf{A}$ . GF may be NULL.
weights	(numeric, $n$ ) a vector of weights, may be NULL.
nIter, burnIn, thin	(integer) the number of iterations, burn-in and thinning.
saveAt	(string) this may include a path and a pre-fix that will be added to the name of the files that are saved as the program runs.
prior	(list) containing the following elements,

- `prior$varE`, `prior$varBR`, `prior$varU`: (list) each providing degree of freedom (`$df`) and scale (`$S`). These are the parameters of the scaled inverse- $\chi^2$  distributions assigned to variance components, see Eq. (2) below. In the parameterization used by `BLR()` the prior expectation of variance parameters is  $S/(df - 2)$ .
  - `prior$lambda`: (list) providing `$value` (initial value for  $\lambda$ ); `$type` ('random' or 'fixed') this argument specifies whether  $\lambda$  should be kept fixed at the value provided by `$value` or updated with samples from the posterior distribution; and, either `$shape` and `$rate` (this when a Gamma prior is desired on  $\lambda^2$ ) or `$shape1`, `$shape2` and `$max`, in this case  $p(\lambda | \max, \alpha_1, \alpha_2) \propto \text{Beta}(\frac{\lambda}{\max} | \alpha_1, \alpha_2)$ . For detailed description of these priors see de los Campos *et al.* (2009).
- `thin2` This value controls whether the running means are saved to disk or not. If `thin2` is greater than `nIter` the running means are not saved (default, `thin2`= $1 \times 10^{10}$ ).
- `minAbsBeta` The minimum absolute value of the components of  $\beta_L$  to avoid numeric problems when sampling from  $\tau^2$ , default  $1 \times 10^{-9}$

## Details

The program runs a Gibbs sampler for the Bayesian regression model described below.

**Likelihood.** The equation for the data is:

$$\mathbf{y} = \mathbf{1}\mu + \mathbf{X}_F\beta_F + \mathbf{X}_R\beta_R + \mathbf{X}_L\beta_L + \mathbf{Z}\mathbf{u} + \boldsymbol{\varepsilon} \quad (1)$$

where  $\mathbf{y}$ , the response is a  $n \times 1$  vector (NAs allowed);  $\mu$  is an intercept;  $\mathbf{X}_F$ ,  $\mathbf{X}_R$ ,  $\mathbf{X}_L$  and  $\mathbf{Z}$  are incidence matrices used to accommodate different types of effects (see below), and;  $\boldsymbol{\varepsilon}$  is a vector of model residuals assumed to be distributed as  $\boldsymbol{\varepsilon} \sim N(\mathbf{0}, \text{Diag}(\sigma_\varepsilon^2/w_i^2))$ , here  $\sigma_\varepsilon^2$  is an (unknown) variance parameter and  $w_i$  are (known) weights that allow for heterogeneous-residual variances.

Any of the elements in the right-hand side of the linear predictor, except  $\mu$  and  $\boldsymbol{\varepsilon}$ , can be omitted; by default the program runs an intercept model.

**Prior.** The residual variance is assigned a scaled inverse- $\chi^2$  prior with degree of freedom and scale parameter provided by the user, that is,  $\sigma_\varepsilon^2 \sim \chi^{-2}(\sigma_\varepsilon^2 | df_\varepsilon, S_\varepsilon)$ . The regression coefficients  $\{\mu, \beta_F, \beta_R, \beta_L, \mathbf{u}\}$  are assigned priors that yield different type of shrinkage. The intercept and the vector of regression coefficients  $\beta_F$  are assigned flat priors (i.e., estimates are not shrunk). The vector of regression coefficients  $\beta_R$  is assigned a Gaussian prior with variance common to all effects, that is,  $\beta_{R,j} \stackrel{iid}{\sim} N(0, \sigma_{\beta_R}^2)$ . This prior is the Bayesian counterpart of Ridge Regression. The variance parameter  $\sigma_{\beta_R}^2$ , is treated as unknown and it is assigned a scaled inverse- $\chi^2$  prior, that is,  $\sigma_{\beta_R}^2 \sim \chi^{-2}(\sigma_{\beta_R}^2 | df_{\beta_R}, S_{\beta_R})$  with degrees of freedom  $df_{\beta_R}$ , and scale  $S_{\beta_R}$  provided by the user.

The vector of regression coefficients  $\beta_L$  is treated as in the Bayesian LASSO of Park and Casella (2008). Specifically,

$$p(\beta_L, \tau^2, \lambda | \sigma_\varepsilon^2) = \left\{ \prod_k N(\beta_{L,k} | 0, \sigma_\varepsilon^2 \tau_k^2) \text{Exp}(\tau_k^2 | \lambda^2) \right\} p(\lambda),$$

where,  $\text{Exp}(\cdot)$  is an exponential prior and  $p(\lambda)$  can either be: (a) a mass-point at some value (i.e., fixed  $\lambda$ ); (b)  $p(\lambda^2) \sim \text{Gamma}(r, \delta)$  this is the prior suggested by Park and Casella (2008); or, (c)  $p(\lambda | \max, \alpha_1, \alpha_2) \propto \text{Beta}(\frac{\lambda}{\max} | \alpha_1, \alpha_2)$ , see de los Campos *et al.* (2009) for details. It can be shown that the marginal prior of regression coefficients  $\beta_{L,k}$ ,  $\int N(\beta_{L,k} | 0, \sigma_\varepsilon^2 \tau_k^2) \text{Exp}(\tau_k^2 | \lambda^2) \partial \tau_k^2$ ,

is Double-Exponential. This prior has thicker tails and higher peak of mass at zero than the Gaussian prior used for  $\beta_R$ , inducing a different type of shrinkage.

The vector  $\mathbf{u}$  is used to model the so called ‘infinitesimal effects’, and is assigned a prior  $\mathbf{u} \sim N(\mathbf{0}, \mathbf{A}\sigma_u^2)$ , where,  $\mathbf{A}$  is a positive-definite matrix (usually a relationship matrix computed from a pedigree) and  $\sigma_u^2$  is an unknown variance, whose prior is  $\sigma_u^2 \sim \chi^{-2}(\sigma_u^2 | df_u, S_u)$ .

Collecting the above mentioned assumptions, the posterior distribution of model unknowns,  $\boldsymbol{\theta} = \{\mu, \beta_F, \beta_R, \sigma_{\beta_R}^2, \beta_L, \tau^2, \lambda, \mathbf{u}, \sigma_u^2, \sigma_\epsilon^2\}$ , is,

$$\begin{aligned}
 p(\boldsymbol{\theta} | \mathbf{y}) &\propto N\left(\mathbf{y} | \mathbf{1}\mu + \mathbf{X}_F\beta_F + \mathbf{X}_R\beta_R + \mathbf{X}_L\beta_L + \mathbf{Z}\mathbf{u}; \text{Diag}\left\{\frac{\sigma_\epsilon^2}{w_i^2}\right\}\right) \\
 &\times \left\{ \prod_j N\left(\beta_{R,j} | 0, \sigma_{\beta_R}^2\right) \right\} \chi^{-2}\left(\sigma_{\beta_R}^2 | df_{\beta_R}, S_{\beta_R}\right) \\
 &\times \left\{ \prod_k N\left(\beta_{L,k} | 0, \sigma_\epsilon^2 \tau_k^2\right) \text{Exp}\left(\tau_k^2 | \lambda^2\right) \right\} p(\lambda) \\
 &\times N(\mathbf{u} | \mathbf{0}, \mathbf{A}\sigma_u^2) \chi^{-2}(\sigma_u^2 | df_u, S_u) \chi^{-2}(\sigma_\epsilon^2 | df_\epsilon, S_\epsilon)
 \end{aligned} \tag{2}$$

### Value

A list with posterior means, posterior standard deviations, and the parameters used to fit the model:

\$yHat	the posterior mean of $\mathbf{1}\mu + \mathbf{X}_F\beta_F + \mathbf{X}_R\beta_R + \mathbf{X}_L\beta_L + \mathbf{Z}\mathbf{u} + \boldsymbol{\epsilon}$ .
\$SD.yHat	the corresponding posterior standard deviation.
\$mu	the posterior mean of the intercept.
\$varE	the posterior mean of $\sigma_\epsilon^2$ .
\$bR	the posterior mean of $\beta_R$ .
\$SD.bR	the corresponding posterior standard deviation.
\$varBr	the posterior mean of $\sigma_{\beta_R}^2$ .
\$bL	the posterior mean of $\beta_L$ .
\$SD.bL	the corresponding posterior standard deviation.
\$tau2	the posterior mean of $\tau^2$ .
\$lambda	the posterior mean of $\lambda$ .
\$u	the posterior mean of $\mathbf{u}$ .
\$SD.u	the corresponding posterior standard deviation.
\$varU	the posterior mean of $\sigma_u^2$ .
\$fit	a list with evaluations of effective number of parameters and DIC (Spiegelhalter <i>et al.</i> , 2002).
\$whichNa	a vector indicating which entries in $\mathbf{y}$ were missing.
\$prior	a list containing the priors used during the analysis.
\$weights	vector of weights.
\$fit	list containing the following elements, <ul style="list-style-type: none"> <li>\$logLikAtPostMean: log-likelihood evaluated at posterior mean.</li> <li>\$postMeanLogLik: the posterior mean of the Log-Likelihood.</li> <li>\$pD: estimated effective number of parameters, Spiegelhalter <i>et al.</i> (2002).</li> <li>\$DIC: the deviance information criterion, Spiegelhalter <i>et al.</i> (2002).</li> </ul>
\$nIter	the number of iterations made in the Gibbs sampler.

\$burnIn            the nuber of iteratios used as burn-in.  
 \$thin             the thin used.  
 \$y                original data-vector.

The posterior means returned by BLR are calculated after burnIn is passed and at a thin as specified by the user.

**Save.** The routine will save samples of  $\mu$ , variance components and  $\lambda$  and running means (rm\*.dat). Running means are computed using the thinning specified by the user (see argument thin above); however these running means are saved at a thinning specified by argument thin2 (by default, thin2= $1 \times 10^{10}$  so that running means are computed as the sampler runs but not saved to the disc).

mice

*mice dataset*

---

## Description

The mice data comes from an experiment carried out to detect and locate QTLs for complex traits in a mice population (Valdar et al. 2006a; 2006b). This data has already been analyzed for comparing genome-assisted genetic evaluation methods (Legarra et al. 2008). The data file consists of 1814 individuals, each genotyped for 10,346 polymorphic markers. The trait here here is body mass index (BMI), and additional information about body weight, season, month and day.

## Usage

```
data(mice)
```

## Format

Matrix mice.A contains the pedigree. The matrix mice.X contains the markes information and mice.pheno contains phenotypical information.

---

read\_bed

*read\_bed*

---

**Description**

This function reads genotype information stored in binary PED (BED) files used in plink. These files save space and time. The pedigree/phenotype information is stored in a separate file (\*.fam) and the map information is stored in an extended MAP file (\*.bim) that contains information about the allele names, which would otherwise be lost in the BED file. More details <http://pngu.mgh.harvard.edu/~purcell/plink/binary.shtml>.

**Usage**

```
read_bed(bed_file,bim_file,fam_file,na.strings,verbose)
```

**Arguments**

bed_file	binary file with genotype information.
bim_file	text file with pedigree/phenotype information.
fam_file	text file with extended map information.
na.strings	missing value indicators, default=c("0","-9").
verbose	logical, if true print hex dump of bed file.

**Value**

The routine will return a vector of dimension  $n \times p$  ( $n$ =number of individuals,  $p$ =number of snps), with the snps(individuals) stacked, depending whether the BED file is in SNP-major or individual-major mode.

The vector contains integer codes:

Integer code	Genotype
0	00 Homozygote "1"/"1"
1	01 Heterozygote
2	10 Missing genotype
3	11 Homozygote "2"/"2"

**Author(s)**

Gustavo de los Campos, Paulino Perez Rodriguez,

**Examples**

```
## Not run:

library(BGLR)
demo(read_bed)

## End(Not run)
```

---

read\_ped

---

*read\_ped*

---

**Description**

This function reads genotype information stored in PED format used in plink.

**Usage**

```
read_ped(ped_file)
```

**Arguments**

ped\_file            ASCII file with genotype information.

**Details**

The PED file is a white-space (space or tab) delimited file: the first six columns are mandatory:

Family ID Individual ID Paternal ID Maternal ID Sex (1=male; 2=female; other=unknown) Phenotype

The IDs are alphanumeric: the combination of family and individual ID should uniquely identify a person. A PED file must have 1 and only 1 phenotype in the sixth column. The phenotype can be either a quantitative trait or an affection status column.

**Value**

The routine will return a vector of dimension  $n \times p$  ( $n$ =number of individuals,  $p$ =number of snps), with the snps stacked.

The vector contains integer codes:

Integer code	Genotype
0	00 Homozygote "1"/"1"
1	01 Heterozygote
2	10 Missing genotype
3	11 Homozygote "2"/"2"

**Author(s)**

Gustavo de los Campos, Paulino Perez Rodriguez,

**Examples**

```
## Not run:

library(BGLR)
demo(read_ped)

## End(Not run)
```

---

wheat

---

*wheat dataset*

---

**Description**

Information from a collection of 599 historical CIMMYT wheat lines. The wheat data set is from CIMMYT's Global Wheat Program. Historically, this program has conducted numerous international trials across a wide variety of wheat-producing environments. The environments represented in these trials were grouped into four basic target sets of environments comprising four main agro-climatic regions previously defined and widely used by CIMMYT's Global Wheat Breeding Program. The phenotypic trait considered here was the average grain yield (GY) of the 599 wheat lines evaluated in each of these four mega-environments.

A pedigree tracing back many generations was available, and the Browse application of the International Crop Information System (ICIS), as described in [http://cropwiki.irri.org/icis/index.php/TDM\\_GMS\\_Browse](http://cropwiki.irri.org/icis/index.php/TDM_GMS_Browse) (McLaren *et al.* 2005), was used for deriving the relationship matrix  $A$  among the 599 lines; it accounts for selection and inbreeding.

Wheat lines were recently genotyped using 1447 Diversity Array Technology (DArT) generated by Triticate Pty. Ltd. (Canberra, Australia; <http://www.triticate.com.au>). The DArT markers may take on two values, denoted by their presence or absence. Markers with a minor allele frequency lower than 0.05 were removed, and missing genotypes were imputed with samples from the marginal distribution of marker genotypes, that is,  $x_{ij} = \text{Bernoulli}(\hat{p}_j)$ , where  $\hat{p}_j$  is the estimated allele frequency computed from the non-missing genotypes. The number of DArT MMs after edition was 1279.

**Usage**

```
data(wheat)
```

**Format**

Matrix Y contains the average grain yield, column 1: Grain yield for environment 1 and so on. The matrix A contains additive relationship computed from the pedigree and matrix X contains the markers information.

**Source**

International Maize and Wheat Improvement Center (CIMMYT), Mexico.

---

wheat.sets

*Sets for cross validation (CV)*

---

**Description**

Is a vector (599 x 1) that assigns observations to 10 disjoint sets; the assignment was generated at random. This is used later to conduct a 10-fold CV.

**Source**

International Maize and Wheat Improvement Center (CIMMYT), Mexico.

---

wheat.X	<i>Molecular markers</i>
---------	--------------------------

---

**Description**

Is a matrix (599 x 1279) with DArT genotypes; data are from pure lines and genotypes were coded as 0/1 denoting the absence/presence of the DArT. Markers with a minor allele frequency lower than 0.05 were removed, and missing genotypes were imputed with samples from the marginal distribution of marker genotypes, that is,  $x_{ij} = \text{Bernoulli}(\hat{p}_j)$ , where  $\hat{p}_j$  is the estimated allele frequency computed from the non-missing genotypes. The number of DArT MMs after edition was 1279.

**Source**

International Maize and Wheat Improvement Center (CIMMYT), Mexico.

---

wheat.Y	<i>Grain yield</i>
---------	--------------------

---

**Description**

A matrix (599 x 4) containing the 2-yr average grain yield of each of these lines in each of the four environments (phenotypes were standardized to a unit variance within each environment).

**Source**

International Maize and Wheat Improvement Center (CIMMYT), Mexico.

---

write_bed	<i>write_bed</i>
-----------	------------------

---

**Description**

This function writes genotype information into a binary PED (BED) file used in plink. For more details about this format see <http://pngu.mgh.harvard.edu/~purcell/plink/binary.shtml>.

**Usage**

```
write_bed(x,n,p,bed_file)
```

**Arguments**

n	integer, number of individuals.
p	integer, number of SNPs.
x	integer vector that contains the genotypic information coded as 0,1,2 and 3 (see details below). The information must be in snp major order. The vector should be of dimension n*p with the snps stacked.
bed_file	output binary file with genotype information.

**Details**

The vector contains integer codes:

Integer code	Genotype
0	00 Homozygote "1"/"1"
1	01 Heterozygote
2	10 Missing genotype
3	11 Homozygote "2"/"2"

**Author(s)**

Gustavo de los Campos, Paulino Perez Rodriguez,

**Examples**
